Fides AI

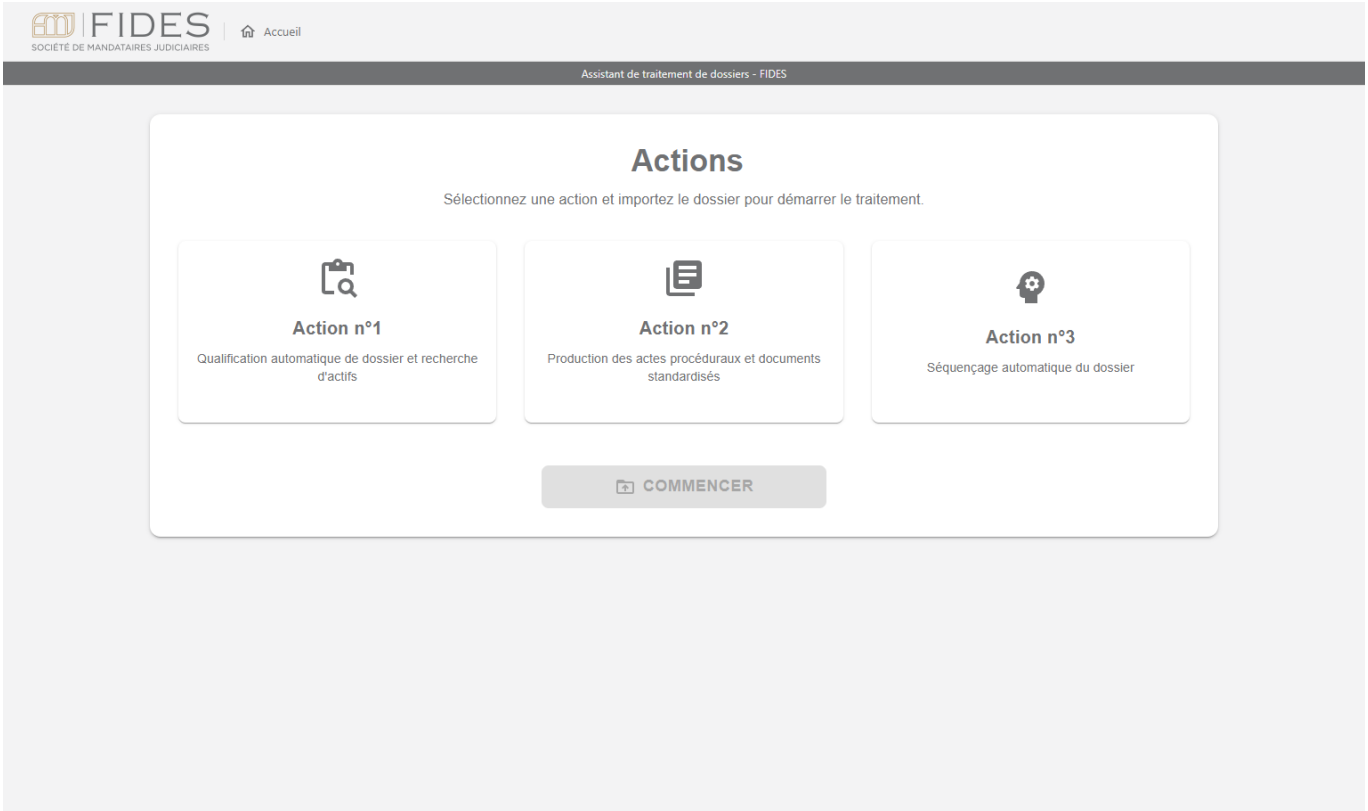
Multi-Agent System for Judicial Case Processing

Fides AI is built as a practical, structured AI system designed for real operational environments.

The project addresses a concrete problem: accelerating the processing of complex judicial cases for court-appointed administrators and trustees using documents, emails, and external data sources. Rather than relying on a generic conversational assistant, the system is designed as a workflow-oriented platform structured around specialized processing steps.

The project combines:

- a specialized multi-agent architecture
- a Python/FastAPI backend API
- a frontend interface to drive workflows and review outputs
- Azure integrations and external business data sources



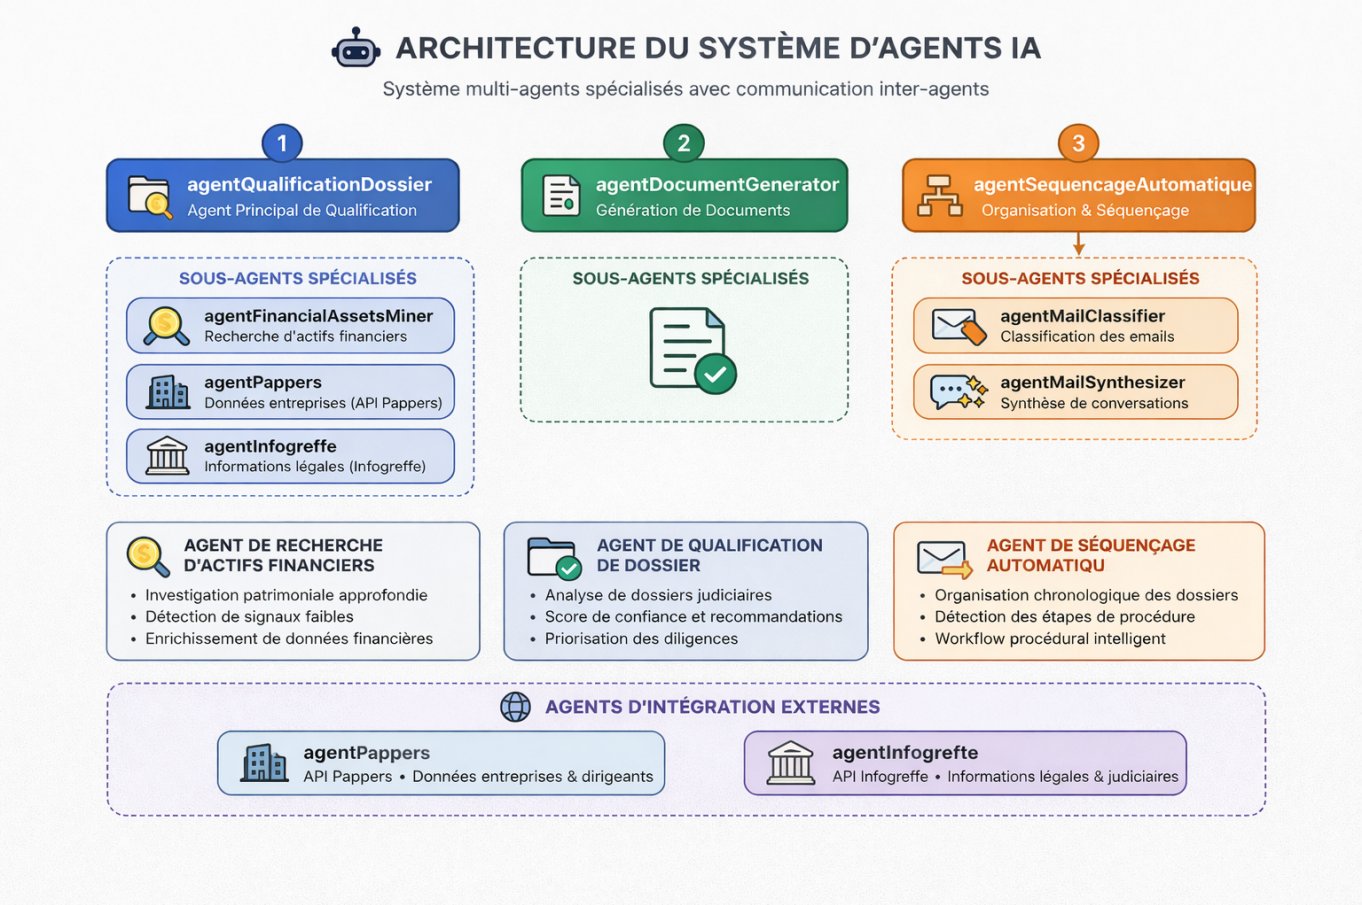
Overview

Judicial case processing relies on heterogeneous inputs: documents, email conversations, internal reference systems, and external data providers. The challenge is not limited to extracting information, but also organizing, qualifying, and presenting it in a directly usable form.

Fides AI is designed as a guided processing system. Each business workflow follows a stable sequence of steps: data retrieval, enrichment, specialized analysis, and final deliverable generation.

Architecture

The architecture is centered around three main agents, supported by specialized sub-agents and external connectors.



agentQualificationDossier

- automatic qualification of a judicial case
- weak-signal aggregation
- diligence prioritization and final report structuring

Associated sub-agents:

- agentFinancialAssetsMiner
- agentPappers
- agentInfogreffe

agentDocumentGenerator

- procedural and standardized document generation
- template selection based on business context
- production of user-reviewable deliverables

agentSequencageAutomatique

- chronological case analysis
- email classification and synthesis
- generation of an actionable sequencing report

Associated sub-agents:

- agentMailClassifier
- agentMailSynthesizer

Business Workflows

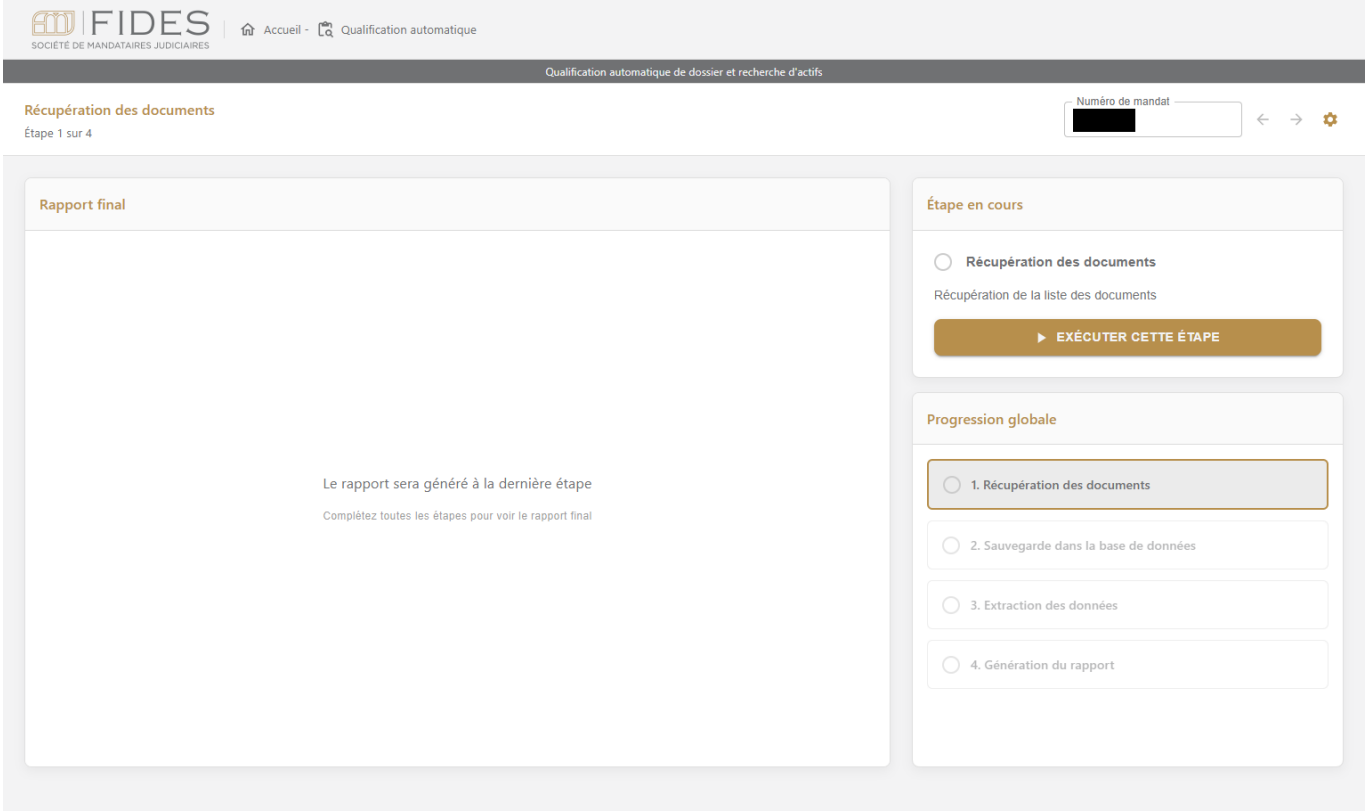
1. Automatic Case Qualification and Asset Discovery

This workflow processes a case mandate, retrieves documents, enriches the case with external sources, detects weak signals, and produces a structured synthesis.

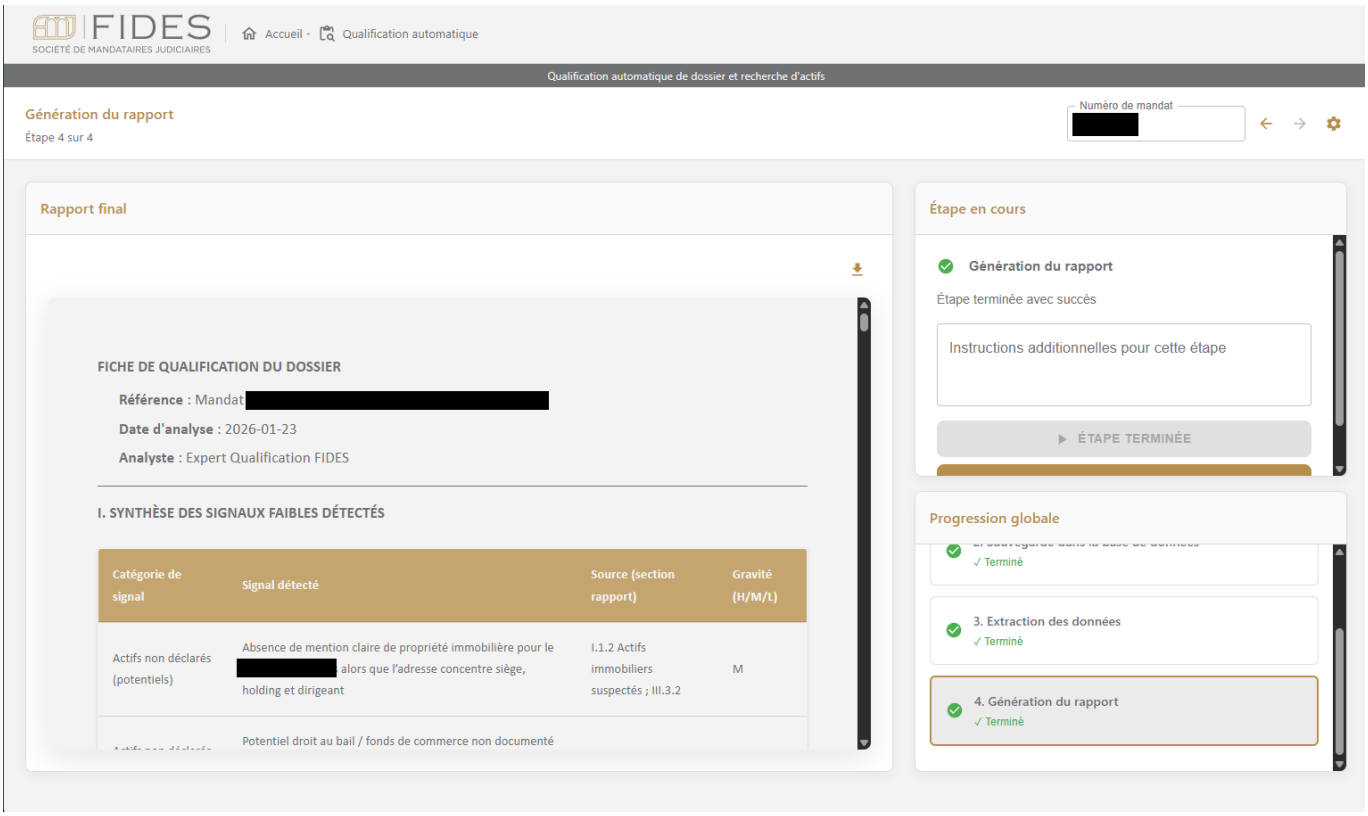
Business pipeline

1. retrieve the list of case documents
2. download and prepare the files
3. perform asset discovery and external enrichment
4. automatically qualify the case
5. generate a consolidated report

Start screen



Generated result



2. Procedural and Standardized Document Generation

This workflow turns a document base into assisted generation of business-ready procedural documents.

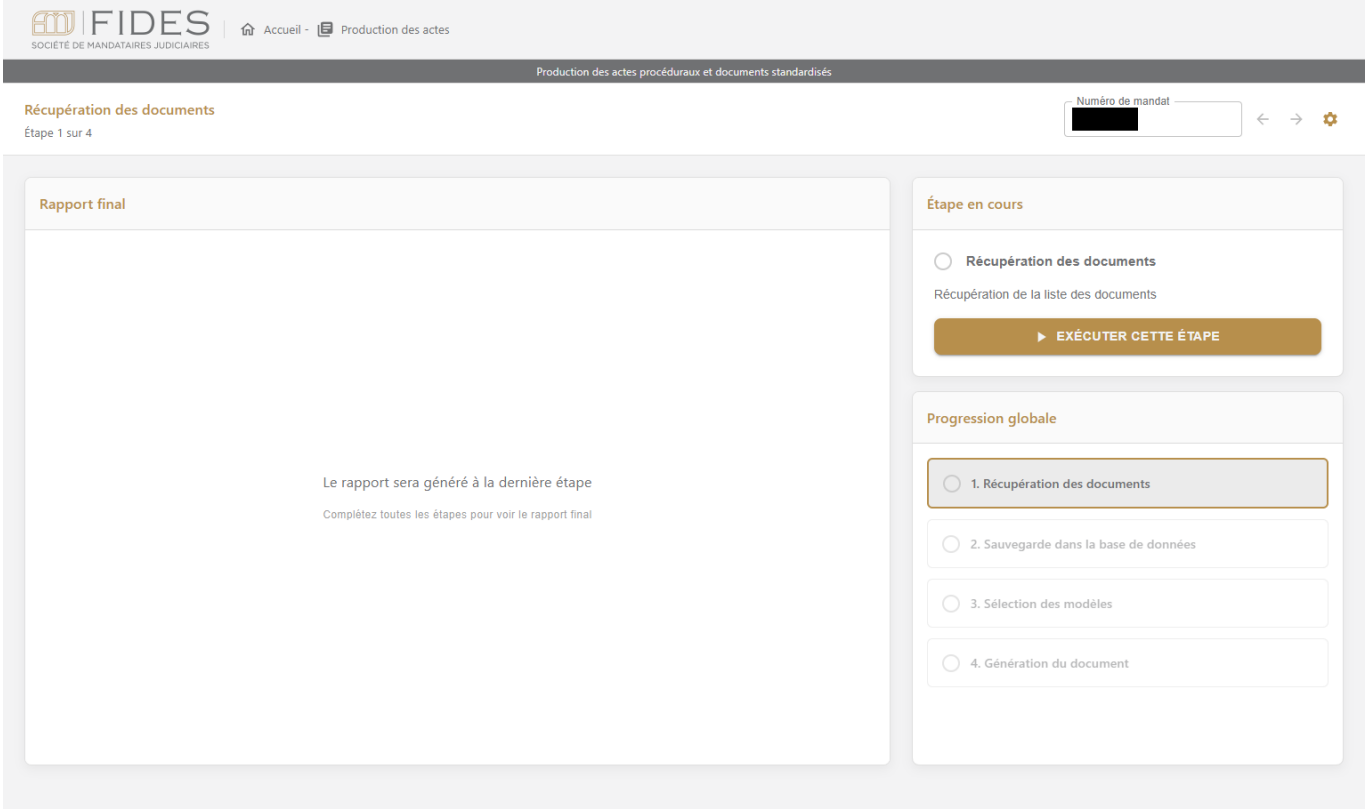
Business pipeline

1. retrieve the documents
2. store and prepare them in the database
3. select a document template
4. generate the final document

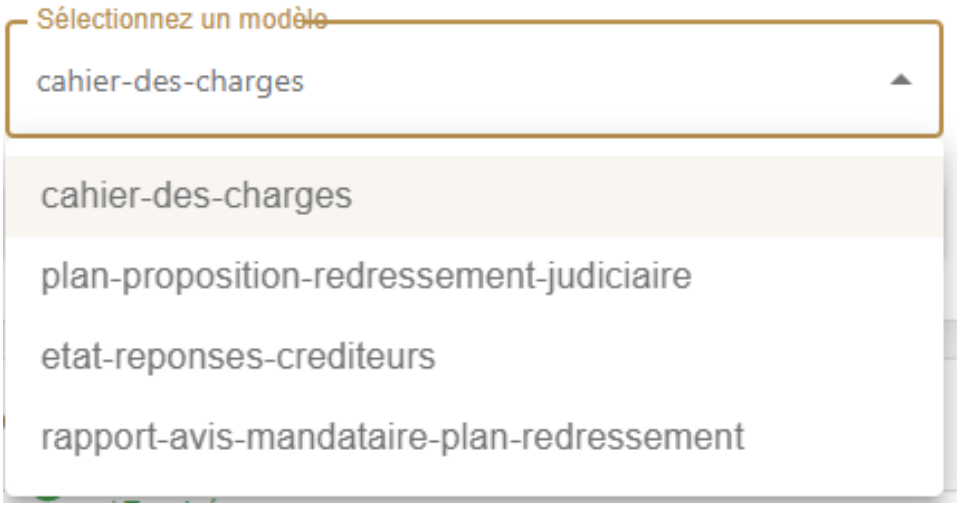
Examples of supported templates

- cahier-des-charges
- plan-proposition-redressement-judiciaire
- etat-reponses-crediteurs
- rapport-avis-mandataire-plan-redressement

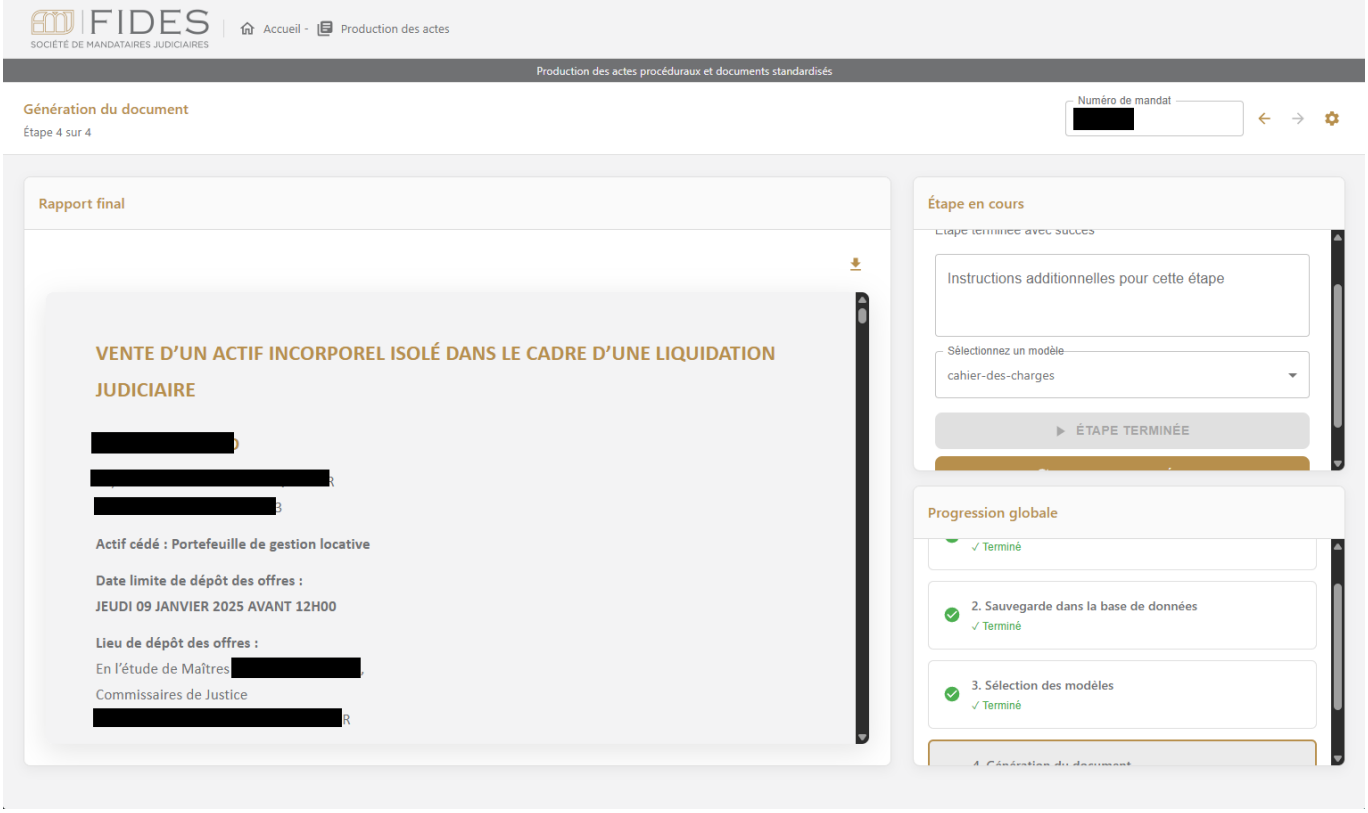
Start screen



Template selection



Generated result



3. Automatic Case Sequencing

This workflow uses case emails to reconstruct procedural history in a fast and readable way.

Business pipeline

1. retrieve the documents
2. store them in the database
3. extract emails
4. classify exchanges automatically
5. generate a chronological synthesis report

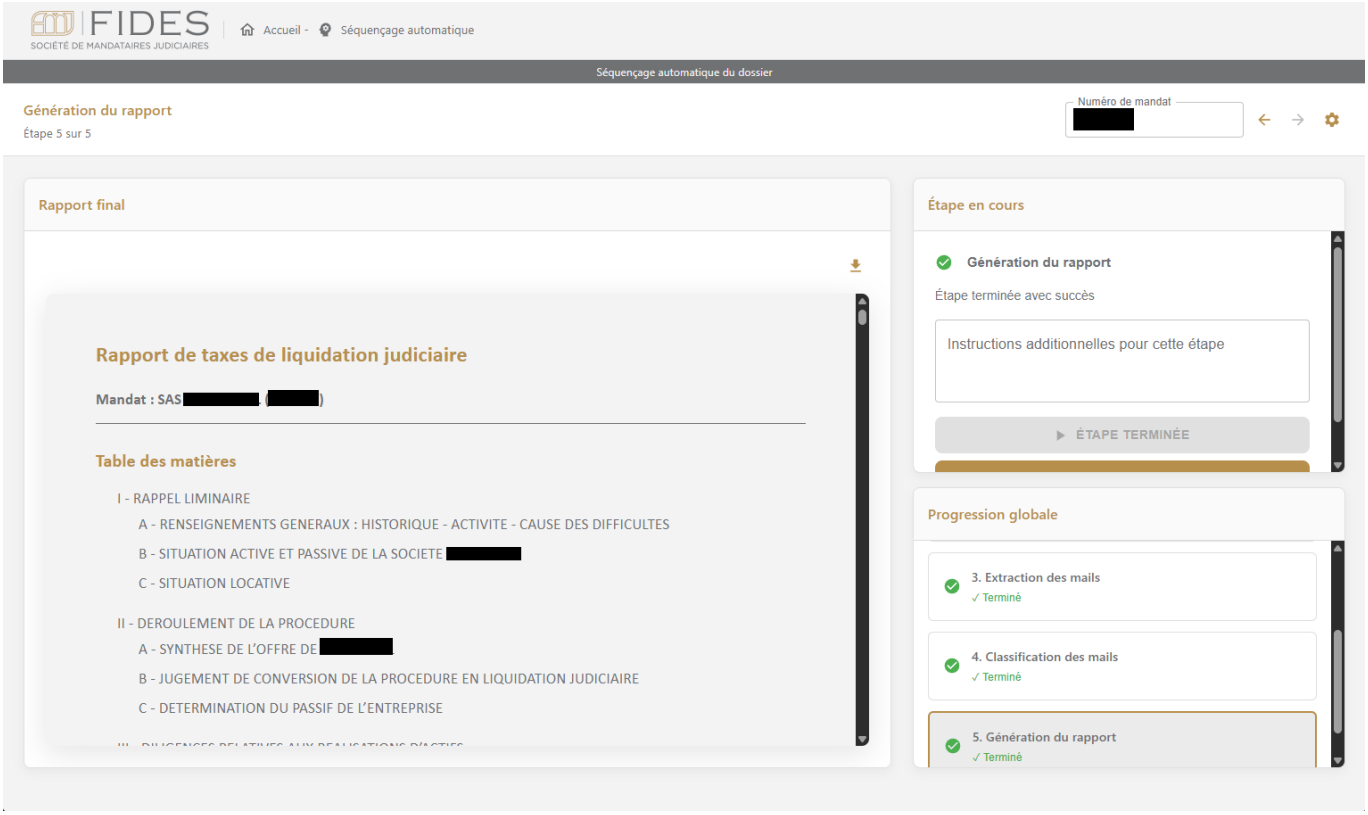
Generated result



Interface and Usage

The interface structures workflow execution, step customization, and result review.

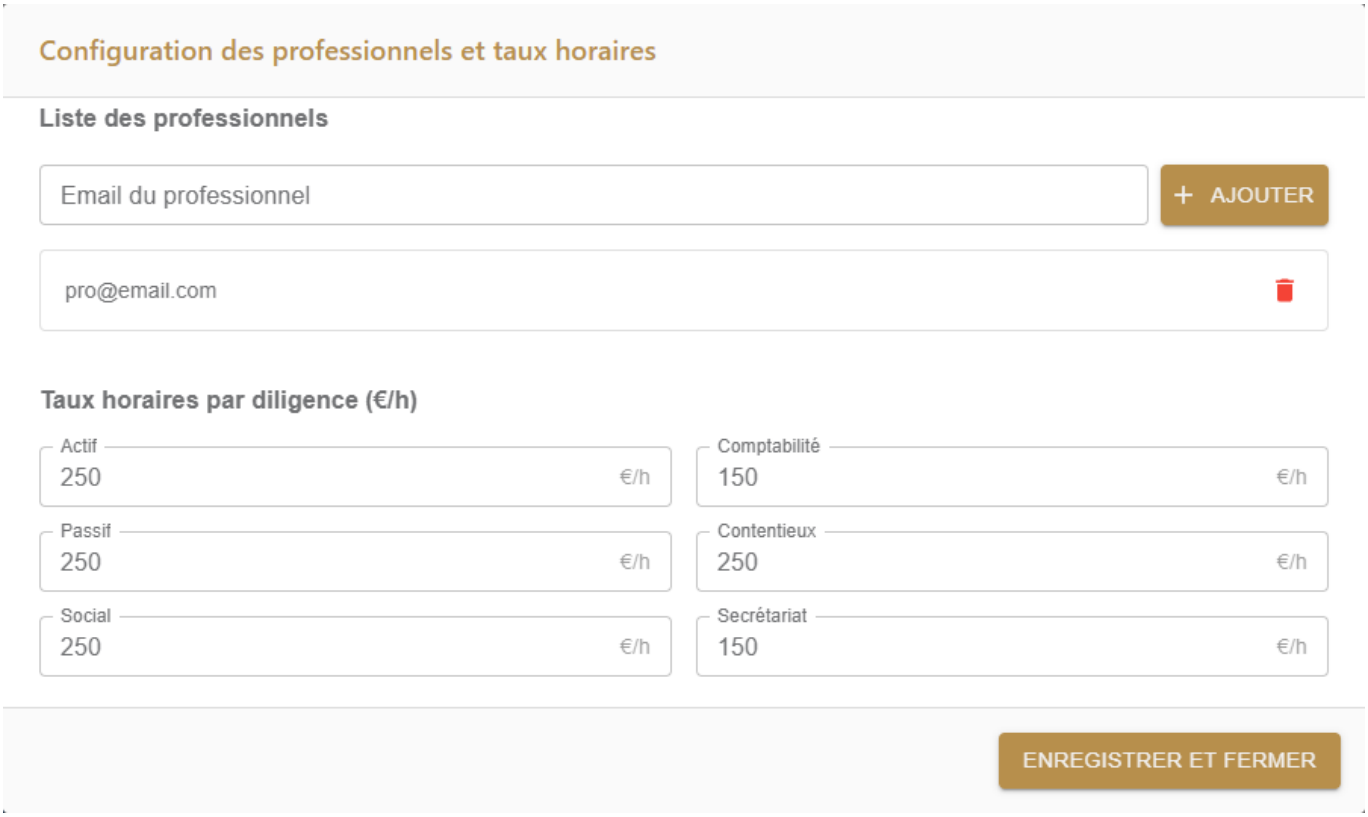
It notably includes:

- step-level custom instructions

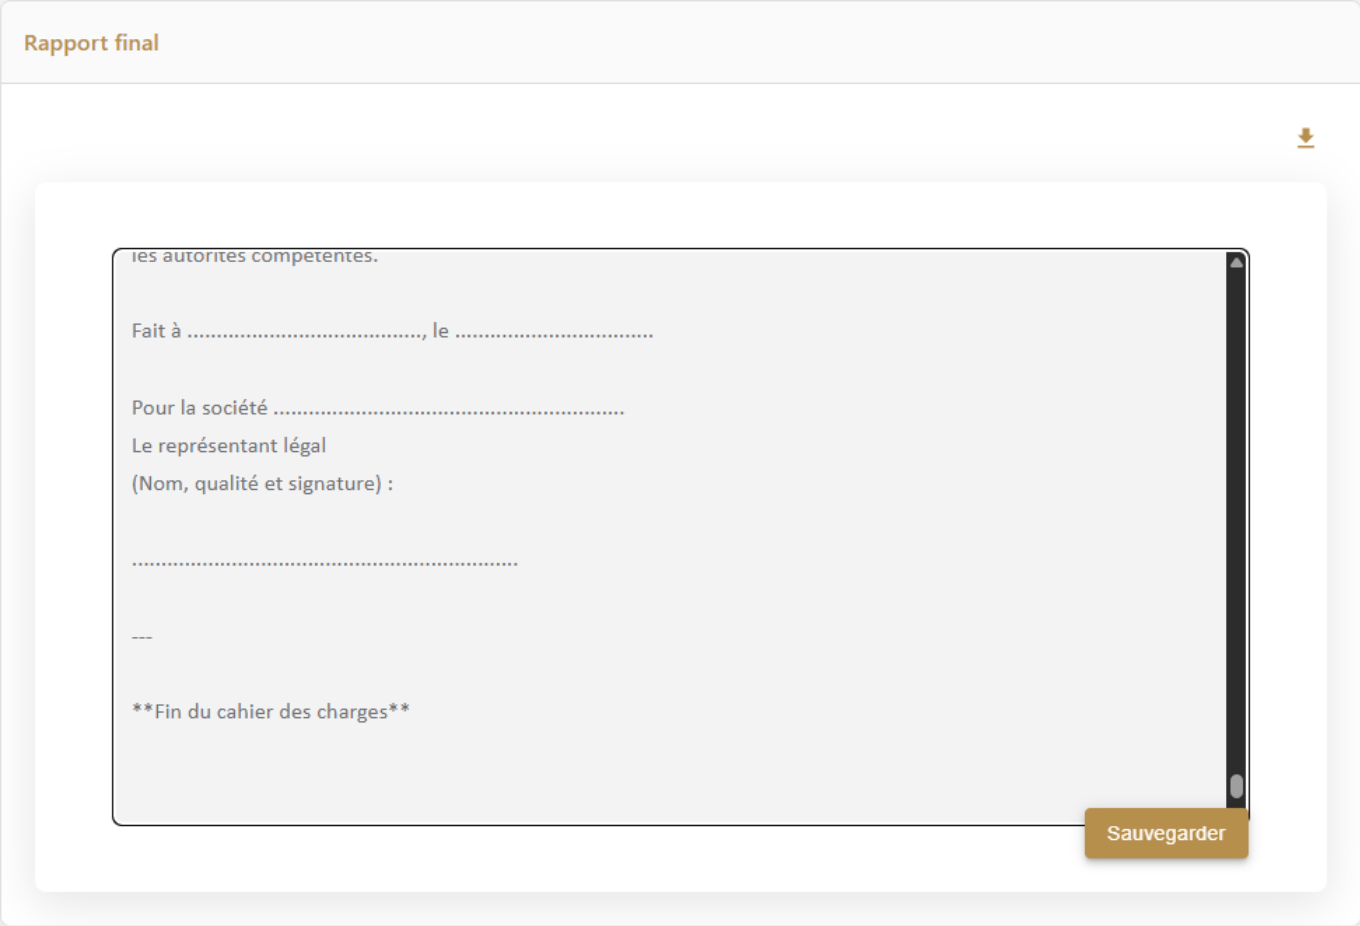
- business configuration parameters such as hourly rates
- final report editing before save or export

Custom instructions

Business configuration



Report editing



Technical Stack

Backend

- Python 3.12+
- FastAPI
- openai-agents
- Azure Cosmos DB
- Azure Blob Storage
- Azure Document Intelligence
- Azure AI Vision
- OpenTelemetry / Azure Monitor

Frontend

- React 19
- React Router 7
- TypeScript
- Material UI
- Vite

Integrations

- Azure OpenAI
- Pappers
- Infogreffe

- Gemarcur

Summary

Fides AI combines a demanding business use case, a multi-agent architecture, full-stack execution, and real integrations. The result is a set of readable workflows and directly usable deliverables.
